

Automated IDE Refactoring Demonstration

This document demonstrates IDE-assisted refactoring using the feature: **Rename Variable**. The example aligns with concepts from Eclipse and IntelliJ IDEA refactoring tutorials.

Before Refactoring (Java Code Example):

```
public class Calculator { public void calculate() { int x = 5; int y = 10; int  
result = x + y; System.out.println(result); } }
```

After Using IDE Rename Feature:

```
public class Calculator { public void calculate() { int numberA = 5; int numberB =  
10; int sum = numberA + numberB; System.out.println(sum); } }
```

Refactoring Steps:

- Eclipse: Right-click variable → Refactor → Rename (or use Alt+Shift+R).
- IntelliJ IDEA: Place cursor on variable → Shift+F6 → type new name → apply.

This refactoring improves readability while keeping behavior identical.
